Nonparametric covariance estimation for longitudinal data via tensor product smoothing

Tayler A. Blake

July 6, 2017

The data:

$$Y_i = (Y_{i1}, Y_{i2}, \dots, Y_{im})', \qquad i = 1, \dots, N$$

associated with measurement times

$$t_1 < t_2 < \cdots < t_m.$$

- ► Covariance matrices (and their estimates) should be positive definite.
 - Constrained optimization is a headache.
- ▶ The $\{t_{ij}\}$ may be suboptimal.
 - Observation times may not fall on a regular grid, may vary across subjects.
- More dimensions, more problems (maybe.)
 - Sample covariance matrix falls apart when m is large

Figure: Regulate like Nate Dogg.

Covariance dress-up: the modified Cholesky decomposition

$$Y = (Y_1, \ldots, Y_M)' \sim \mathcal{N}(0, \Sigma).$$

For any positive definite Σ , we can find T which diagonalizes Σ :

$$D = T\Sigma T', \quad T = \begin{bmatrix} 1 & 0 & \dots & & \\ -\phi_{21} & 1 & & & \\ -\phi_{31} & -\phi_{32} & 1 & & \\ \vdots & & & \ddots & \\ -\phi_{M1} & -\phi_{M2} & \dots & -\phi_{M,M-1} & 1 \end{bmatrix}$$

Now, for the cutest part:

Okay, really:

Imagine regressing Y_i on its predecessors:

$$y_{j} = \begin{cases} e_{1} & j = 1, \\ \sum_{k=1}^{j-1} \phi_{jk} y_{k} + \sigma_{j} e_{j} & j = 2, \dots, M \end{cases}$$
 (1)

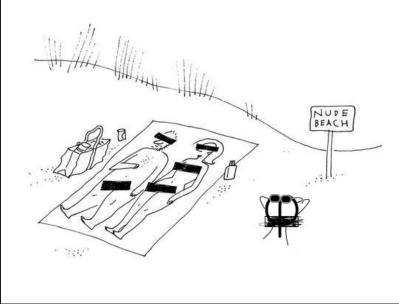

In matrix form:

$$e = TY, (2)$$

and taking covariances on both sides:

$$D = diag\left(\sigma_1^2, \dots, \sigma_M^2\right) = T\Sigma T'. \tag{3}$$

No constraints on the ϕ_{jk} s!

The regression model tool box: a deep treasure chest of luxury.

Model Y_i , e_i as

$$Y_j = Y(t_j), \quad e_j = e(t_j),$$

 $e(s) \sim \mathcal{WN}(0, 1),$

Swap the standard regression model 1 for a varying coefficient model:

$$\phi_{jk} = \phi\left(t_j, t_k\right),\,$$

$$y(t_j) = \sum_{k=1}^{j-1} \phi(t_j, t_k) y(t_k) + \sigma(t_j) e(t_j)$$
 (4)

Penalized maximum likelihood estimation

- 1. Fix $\sigma_{ij}^2 = \sigma_{ij0}^2$, i = 1, ..., N, j = 1, ..., M.
- 2. Find $\phi_0 = \underset{\phi}{arg \ min} 2L_{\phi}\left(\phi, y_1, \dots, y_N\right) + \lambda J\left(\phi\right)$
- 3. Fix $\phi = \phi_0$.
- 4. Find $\sigma_0^2 = \underset{\sigma^2}{arg \ min} 2L_\sigma^2(\sigma^2, y_1, \dots, y_N) + \lambda J(\sigma^2)$

$$-2L_{\phi}(\phi, y_1, \dots, y_N) = \sum_{i=1}^{N} \sum_{j=2}^{m_i} \sigma_{ij0}^{-2} \left(y_{ij} - \sum_{k=1}^{j-1} \phi(t_{ij}, t_{ik}) y_{ik} \right)^2$$

Regularization of $\phi(s,t)$ is more intuitive if we transform the s-t axis.

Rotate the input axes:

$$l = s - t$$

$$m = \frac{1}{2} (s + t).$$

Then ϕ becomes

$$\phi^* (l, m) = \phi^* \left(s - t, \frac{1}{2} (s + t) \right)$$
$$= \phi (s, t).$$

Take $\hat{\phi}^*$ to be the minimizer of

$$-2L + \lambda J\left(\phi^*\right)$$

Smooth ANOVA models

Decompose

$$\phi^*(l,m) = \mu + \phi_1(l) + \phi_2(m) + \phi_{12}(l,m), \tag{6}$$

so Model 4 becomes

$$y(t_{j}) = \sum_{k=1}^{j-1} \left[\mu + \phi_{1}(l_{jk}) + \phi_{2}(m_{jk}) + \phi_{12}(l_{jk}, m_{jk}) \right] y(t_{k}) + \sigma(t_{j}) e(t_{j})$$
(7)

We can use B-splines to construct the model basis.

$$\phi_{1}(l) = \sum_{c=1}^{c_{l}} B_{c}(l; q_{l}) \theta_{lc},$$

$$\phi_{2}(m) = \sum_{c'=1}^{c_{m}} B_{c'}(m; q_{m}) \theta_{mc'},$$
(8)

$$\phi_{12}(l,m) = \sum_{c=1}^{c_l} \sum_{c'=1}^{c_m} B_c(l;q_l) B_{c'}(m;q_m) \theta_{cc'}$$
 (9)

PS-ANOVA model basis

In matrix notation, Model 7 becomes

$$E[Y|W] = WB\theta,$$

where W is the matrix of covariates holding the past values of Y, and B is the B-spline regression basis:

$$B = [1_p \mid B_l \mid B_m \mid B_{lm}] \tag{10}$$

where

$$B_{lm} = B_m \square B_l$$

$$\equiv (B_m \otimes 1'_{c_l}) \odot (1'_{c_m} \otimes B_l).$$

Difference penalty had to regulate.

For
$$f(x) = \sum_{i=1}^{p} B_i(x) \theta_i$$
, approximate

$$\int_{0}^{1} (f''(x))^{2} dx = \int_{0}^{1} \left\{ \sum_{i=1}^{p} B_{i}''(x) \theta_{i} \right\}^{2} dx$$

$$= k_{1} \sum_{i} (\Delta^{2} \theta_{i})^{2} + k_{2},$$
(11)

by

$$||D_2\theta||^2$$
, $D_2\theta = (\Delta^2\theta_1, \dots, \Delta^2\theta_{p-2})'$

In general, approximate $\int_{0}^{1} (f^{(d)})^{2} dx$ with $||D_{d}\theta||^{2}$

PS-ANOVA Penalty

Estimate B-spline coefficients by minimizing

$$(Y - WB\theta)'(Y - WB\theta) + \theta'P\theta$$

where

$$P = blockdiag(0, P_l, P_m, P_{lm}), \qquad (12)$$

$$\begin{split} P_l &= \lambda_l D'_{d_l} D_{d_l} \\ P_m &= \lambda_m D'_{d_m} D_{d_m} \\ P_{12} &= \tau_l D'_{d_l} D_{d_l} \otimes I_{c_m} + \tau_m I_{c_l} \otimes D'_{d_m} D_{d_m} \end{split}$$

Mixed model representation

In matrix notation, Model 7 is given by

$$E[Y|W] = WB\theta,$$

where W is the matrix of covariates holding the past values of Y, and B is the B-spline regression basis:

$$B = [1_p \mid B_l \mid B_m \mid B_{lm}] \tag{13}$$

$$B_{lm} = \left(B_m \otimes 1'_{c_l} \right) \odot \left(1'_{c_m} \otimes B_l \right),\,$$

and

$$\theta = (\mu, \ \theta_l, \ \theta_l, \ \theta_{lm})'$$

Mixed model representation

Find transformation M to map

$$B \longrightarrow [X \mid Z], \qquad \theta \longrightarrow (\beta, \alpha)'$$

such that

$$BM = [X \mid Z], \qquad B\theta = X\beta + Z\alpha$$

Map model

$$Y = W(X\beta + Z\alpha) + e,$$

$$\alpha \sim \mathcal{N}(0, G), \quad e \sim \mathcal{N}(0, D)$$
(14)

Mixed model representation

$$G \longrightarrow F^{-1}$$

$$\theta' P \theta \longrightarrow \alpha' F \alpha$$

$$F = \text{blockdiag}(F_l, F_m, F_{lm}),$$

$$F_l = \lambda_l \tilde{\Delta}_l, \qquad F_l = \lambda_m \tilde{\Delta}_m,$$

$$F_{lm} = \begin{bmatrix} \tau_l \tilde{\Delta}_l \\ \\ \tau_m \tilde{\Delta}_m \\ \\ \end{bmatrix}$$

$$\tau_m \tilde{\Delta}_m \otimes I_{c_l - d_l} + I_{c_m - d_m} \otimes \tau_l \tilde{\Delta}_l$$

Decomposition of ϕ^* for $d_l = d_m = 2$

	{1}	$\{m\}$	$\left\{ B_{j^{\prime}}\left(m ight) ight\}$
{1}	{1}	$\{m\}$	$\left\{ B_{j^{\prime}}\left(m ight) ight\}$
$\{l\}$	$\{l\}$	$l \times m$	$l \times \{B_{j'}(m)\}$
$\{B_{j}\left(l\right)\}$	$\{B_{j}\left(l\right)\}$	$m \times \{B_j(l)\}$	$\left\{ B_{j}\left(l\right) B_{j^{\prime}}\left(m ight) ight\}$

Re-express ϕ_{12} :

$$\phi_{12}(l,m) = g_1(l) \left[\sum_{r=1}^{d_{m-1}} m^r \right] + \left[\sum_{r=1}^{d_l-1} l^r \right] g_2(m) + h(l,m),$$

For $d_l = d_m = 2$,

$$\phi_{12}(l,m) = g_1(l) \ m + l \ g_2(m) + h(l,m)$$

with basis:

$$B = [1_p \mid B_1 \mid B_2 \mid B_3 \mid B_4 \mid B_5], \tag{15}$$

where

$$B_3 = m \square B_1 \qquad B_5 = B_2 \square B_1$$

$$B_4 = B_2 \square l$$

$$P = \text{blockdiag}(0, P_1, P_2, P_3, P_4, P_5),$$
 (16)

Re-express ϕ_{12} :

$$\phi_{12}(l,m) = g_{lr}(l) \left[\sum_{r=1}^{d_{m-1}} m^r \right] + \left[\sum_{r=1}^{d_l-1} l^{r'} \right] g_{mr'}(m) + h(l,m),$$

For $d_l = d_m = 2$,

$$\phi_{12}(l,m) = g_{l1}(l) \ m + l \ g_{m1}(m) + h(l,m)$$

with basis:

$$B = [1_p \mid B_1 \mid B_2 \mid B_3 \mid B_4 \mid B_5], \tag{17}$$

where

$$B_3 = m \square B_1 \qquad B_5 = B_2 \square B_1$$

$$B_4 = B_2 \square l$$

$$P = blockdiag(0, P_1, P_2, P_3, P_4, P_5)$$

Remove the redundant columns, and give each penalized component its own random effect:

B
